Productivity and Development Issues of Global Wind Turbine Industry

Ali Mostafaeipour

Industrial Engineering Department, Yazd University, Yazd, Iran

1. Introduction

Renewable energies (REs) represent a cornerstone to steer our energy system in the direction of sustainability and supply security and a broad set of different RE technologies and resources exist today [1]. Wind is one of the world's fastest growing renewable energy sources. The rapid growth in wind power is a result of improvements accomplished in technology [2]. The recent focus on finding solutions for mitigating global warming has resulted in renewable energy technologies gaining importance. Among the renewable energy technologies, wind power is one of the fastest growing technologies globally at an average annual growth rate of more than 26% since 1990 [3, 4].

The worldwide demand for renewable energy is increasing rapidly because of the climate problem, and also because oil resources are limited. Wind energy appears as a clean and good solution to cope with a great part of this energy demand [5]. Developing a utility-scale wind project is a complicated and time-consuming process involving developers, landowners, utilities, the public and various local authorities. Although each wind energy project is unique and have different characteristics, basic features and related steps are common [2]. In practice, the steps are iterative and overlap one another depending on the specific project circumstances. The key steps of development and planning for a wind farm are site selection, detailed wind assessment, feasibility, construction and operation [2, 6].

Estimates of the global technical potential of solar energy range from 15 to 4300 EJ, and for on-shore wind 3–600 EJ [7, 8, 9]. Over three quarters of global wind turbine sales come from only four turbine manufacturing companies: Vestas, GE Wind, Enercon, and Gamesa [10].

The Intergovernmental Panel on Climate Change (IPCC) in 2001 [11], for example, estimated the annual global theoretical terrestrial potential of wind as 1728 EJ from all land with mean annual wind speeds >5.1 m/s at 10m above the ground. This amount was then reduced to give a technical potential of only 72 EJ based on the experience of the Netherlands and the USA [7]. As a resource, wind energy offers a number of advantages over solar energy. Peak energy intensity for wind turbines is currently around 400 W/m^2 , more than twice that for solar PV [7].

Energy is one of the essential inputs for economic development and industrialization. Fossil fuels are the main resources and play a crucial role to supply world energy demand. However fossil fuel reserves are limited and usage of fossil fuel sources have negative environmental impacts. Therefore, management of energy sources, rational utilization of energy, and renewable energy source usage are vital. Since the first oil crisis, renewable

energy sources have gained a great importance due to their inexhaustibility, sustainability, ecological awareness and supply of energy security. So, renewable energy sources are expected to play an important role especially in electrical energy generation [12].

Among the renewable energy sources wind energy is currently viewed as one of the most significant, fastest growing, commonly used and commercially attractive source to generate electrical energy because of the mature and cost effective energy conversion system technology. So, electricity generation cost from wind energy system has become competitive with fossil fuel systems. Installed total wind power capacity has reached over 93 GW and installed wind power capacity generates more than 1% of the global electricity consumption. In recent years Weibull distribution has been one of the most commonly used, accepted, recommended distribution to determine wind energy potential and it is also used as a reference distribution for commercial wind energy softwares such as Wind Atlas Analysis and Application Program (WAsP) [12,13,14,15]. Germany is a leader in Europe on shifting from conventional to renewable sources of energy. As its land-based sites of wind energy are built to capacity [16,17], Germany looks to the sea for further production possibilities. In the United States and Germany, offshore areas are generally considered public space, which makes offshore renewable energy development public in nature [18].

Many countries and sub-national governments are looking not only to expand their domestic use of renewable energy, but also to develop accompanying local renewable energy technology manufacturing industries to serve that demand [18]. Cost is a central issue in meeting greenhouse gas emission reduction goals [19, 20]. Some clean energy technologies are relatively costly today but costs may decrease over time as technological improvements occur, equipment is standardized, and economies of scale take hold [20].

Electricity generated from wind power currently represents only 0.5 percent of global electricity production, and about a 7 billion (US) dollar annual industry [23]. The market is expected to double over the next 4 years [10], and it is this perceived potential for future growth and the rapid growth rates to date that are causing many governments to look toward developing domestic wind technology manufacturing industries. Countries and sub-national governments around the world – in both developed and developing countries – are therefore establishing policies to promote the construction of new wind power installations, and some have developed targeted policies to specifically encourage local manufacturing of large wind turbine technology [25]. The reasons why it is difficult to quantify the exact number of jobs coming from wind-related activities have to do with the lack of detail in the official statistics, which does not allow researchers to exploit the data, and with the variety of company profiles that make up the sector, which can be hard to identify and examine. The wind energy sector has grown exponentially since the end of the 1990s, especially within the European Union (EU), and this has affected the employment levels of the regions involved [26].

2. Global installed wind turbines and energy potential

A reliable supply of energy is essential to maintain and to improve human being's living conditions. Compared to the conventional coal-fired approach, renewable energy (RE) helps to mitigate the impacts of greenhouse gas emissions to a large extent. According to the Global Wind Energy Council (GWEC), the global cumulative installed capacity has reached 94 GW in 2007, which increased 31% than the previous year [24,27]. Today, the world's energy supply is largely based on fossil fuels and nuclear power. These sources of energy

will not last forever and have proven to be contributors to our environmental problems. The environmental impacts of energy use are not new but they are increasingly well known; they range from deforestation to local and global pollution. In less than three centuries since the industrial revolution, mankind has already burned roughly half of the fossil fuels that accumulated under the earth's surface over hundreds of millions of years. Nuclear power is also based on a limited resource (uranium) and the use of nuclear power creates such incalculable risks that nuclear power plants Cannot be insured [28].

Based on a survey amongst the WWEA (World Wind Energy Association) member associations, a double digit growth for the wind energy market is expected despite the general economic crisis. Based on available figures from 11 of the top 15 countries representing over 80% of the world market, WWEA recorded 5374 MW new installed capacity in the first quarter of 2009, equaling an increase of 23% compared with last year in the same countries. WWEA keeps its previous prevision of a total installed capacity of 152000 MW worldwide by the end of 2009 (Fig. 1), which will mean a new record of over 30,000 MW newly installed capacity within one year. This represents a market growth of 25% compared with last year [29].

Based upon the World Wind Energy Report in 2008, following global highlights is important [30]:

- Worldwide capacity reaches 121188 MW, out of which 27261 MW were added in 2008.
- Wind energy continued its growth in 2008 at an increased rate of 29 %.
- All wind turbines installed by the end of 2008 worldwide are generating 260 TWh per annum, equaling more than 1.5 % of the global electricity consumption.
- The wind sector became a global job generator and has created 440'000 jobs worldwide.
- The wind sector represented in 2008 a turnover of 40 billion Euros.
- For the first time in more than a decade, the USA took over the number one position from Germany in terms of total installations.
- China continues its role as the most dynamic wind market in the year 2008, more than doubling the installations for the third time in a row, with today more than 12 GW of wind turbines installed.
- North America and Asia catch up in terms of new installations with Europe which shows stagnation.
- Based on accelerated development and further improved policies, a global capacity of more than 1,500,000 MW is possible by the year 2020.

The status of wind energy is as a stable, profitable and low-risk investment. Although some wind energy projects are postponed due to financing challenges, the overall market development can still compensate such delays showing great signs of vitality. A substantial share of the slow down in some regions are a consequence of new regulations and bureaucratic delays that undermine the development of new wind parks rather than of financing difficulties [29].

Areas of potential wind turbine improvements include [21, 22]:

- Advanced tower designs, including taller towers, new materials, and telescoping towers that are easier to install.
- Larger rotors made from lighter materials and having improved aerodynamics.
- More efficient gear boxes, drive trains, generators, and electronics.

Renewable sources of energy are essential parts of an overall strategy of sustainable development. They help reduce dependence of energy imports, thereby ensuring a sustainable supply. Furthermore renewable energy sources can help improve the competitiveness of industries over the long run and have a positive impact on regional development and employment. Renewable energy technologies are suitable for off-grid services, serving those in remote areas of the world without requiring expensive and complicated grid infrastructure [28].

*= Prediction

Fig. 1. Total world installed capacity [30].

2.1 Energy potential

The theoretical potential of wind energy as illustrated in Table 1 amounts to 6,000 EJ (or more than 12 times current energy needs), what seems to be enormously high when compared to its current use. A technical potential is estimated to be 10% of the theoretical one. The ultimate potential of wind-generated electricity worldwide could indeed be very large: Other assessments state figures of up to 50 times current global final electricity consumption [1, 33, 34, and 35]. Height limitations of wind converters, coast distance of offshore sites, insufficient wind velocities and land use, and the feasible grid integration all limit the realizable potential of this promising technology option.

2.1.1 Technical potential

If technical boundary conditions (i.e. efficiencies of conversion technologies, overall technical limitations as, e.g. the available land area to install wind turbines) are considered the technical potential can be derived.

2.1.2 Theoretical potential

For deriving the theoretical potential general physical parameters have to be taken into account (e.g. based on the determination of the energy flow resulting from a certain energy

resource within the investigated region). It represents the upper limit of what can be produced from a certain energy resource from a theoretical point-of-view – of course, based on current scientific knowledge [1].

Potential for geothermal energy is higher than other resources of energy, but its use was only 2 EJ in 2004 which is very low.

Potential for biomass energy is 2900 EJ, but its use was 50 EJ in 2004 which was highest if we compare with other resources of energy in the world.

Resource	Use in 2004 (EJ)	Technical Potential	Theoretical Potential
Biomass	50	250	2900
Geothermal	2	5000	140000000
Hydropower	10	50	150
Ocean	-	-	7400
Solar	0.2	1600	3900000
Wind	0.2	600	6000
Total	62.4	7500	143916450

Table 1. Technical and theoretical potentials and usage for various renewable energy sources (in terms of primary energy) at global scale [33].

The top five countries in terms of total installed wind capacity at the end of 2004 were Germany, Spain, USA, Denmark, and India; wind turbine manufacturers from these top five countries sold 94 percent of all wind turbines installed globally in 2004. Germany clearly stands out as having maintained the most sizable and stable market [25].

The US and Indian markets have been much less stable than those of Germany, Spain, and Denmark. Annual installations in the US were highest in 2001 and 2003 with over 1,600MW installed each year. However, annual installations dipped well below 200MW per year between 1995 and 1998, and again in 2000. The year 2004 was also slow in the US, as the on-again, off-again nature of the federal production tax credit (PTC) has created significant uncertainty in the market in recent years. India’s market has also been unstable, with initial growth in the mid 1990s, a slowdown in the late 1990s, and some resurgence in recent years. From 2001 to 2004, however, India has been able to maintain annual installations of over 200MW per year. Though the instability of the Indian and US markets has not stopped local investments in wind manufacturing (in part because the long-term market potential is so large in both countries), it has often complicated the process of developing successful local wind manufacturing industries [25].

The Brazilian government has also pursued policies governing wind farm development that include stringent local content requirements, primarily through the recent Proinfa legislation (the Incentive Program for Alternative Electric Generation Sources) that offers fixed-price electricity purchase contracts to selected wind projects. Starting in January 2005, the Proinfa legislation requires 60 percent of the total cost of wind plant goods and services to be sourced in Brazil; only companies that can prove their ability to meet these targets can take part in the project selection process. In addition, from 2007 onwards, this percentage increases to 90 percent [25, 31].

China has also been using local content requirements in a variety of policy forms. China’s 1997 “Ride the Wind Program” established two Sino-foreign joint venture enterprises to domestically manufacture wind turbines; the turbines manufactured by these enterprises

under technology transfer arrangements started with a 20 percent local content requirement and a goal of an increase to 80 percent as learning on the Chinese side progressed [25,32]. China’s recent large government wind tenders, referred to as wind concessions, have a local content requirement that has been increased to 70 percent from an initial 50 percent requirement when the concession program began in 2003. Local content is also required to obtain approval of most other wind projects in the country, with the requirement recently increased from 40 to 70 percent [25].

3. Wind market growth rates

An important indicator for the vitality of the wind market is the growth rate in relation to the installed capacity of the previous year. The growth rate went up steadily since the year 2004, reaching 29.0 % in 2008, after 26.6 % in 2007, 25.6 % in the year 2006 and 23.8 % in 2005. However, this increase in the average growth rate is mainly due to the fact that the two biggest markets showed growth rates far above the average: USA 50 % and China 107 % (Fig. 2). Bulgaria showed the highest growth rate with 177 %, however, starting from a low level. Also Australia, Poland, Turkey and Ireland showed a dynamic growth far above the average [30]. Figure 3 shows that world wind market growth rate in 1999 was the highest and then was decreased to the year 2004 which was the lowest. Since 2004 it has had a slight increase. It is also interesting to know that growth rate for Turkey in 2007 was a lot more than 2008.

Between 1991 and 1995 both the average list price of wind turbines and turnkey investment costs of wind farms in Germany have declined steadily by about 8–9% per year. However, average prices remained rather stable since 1995. In fact, the price of the cheapest turbine available even increased during 1995–1999. There are a number of possible explanations for these trends. In Germany, more and more wind parks are situated in inland areas with

Fig. 2. Top ten countries with highest growth rate [30].

Fig. 3. World market growth rate in % [30].

lower wind speeds, due to a lack of appropriate sites near the coast. While in 1993, 70% of all new wind parks (in terms of capacity) were installed in coastal regions, this share has dropped to a mere 10–15% in 1999 [36,37]. The wind energy sector is one of the fastest-growing energy sectors in the world. From 1991 until the end of 2002, global installed capacity has increased from about 2GW [38] to over 31GW [39], with an average annual growth rate of about 26%. During this period, both prices of wind turbines and cost of wind-generated electricity have been reduced. In spite of these developments, electricity derived from wind is not yet able to fully compete with electricity produced from fossil fuel. However, this may change in the near future [36, 40].

In terms of countries, the ‘big five’ (Germany, Spain, Denmark, the USA and India) have been at the top for the last decade (from 1995 to 2005). In these countries over 80% of the worldwide wind-based power generation capacity was installed in 2005 [36, 39]. The expansion of renewable energies requires additional investments into production facilities as well as into the transportation and distribution grid. Since the majority of renewable energy technologies is not profitable at current energy prices, its furtherance is not only associated with production and employment effects but with increasing cost as well. It is apparent that the cost disadvantage of renewable compared to conventional energies is crucially dependent on future prices of energies used in power plants as well as on the amount of CO₂ emission permits [63, 64].

4. Installed wind turbines worldwide (2007- 2008)

The share of new installed capacity for USA and China with 31.62% and 23.83% respectively accounts for more than half of the other countries in the world for 2008 (Fig 4).

The USA and China took the lead, USA taking over the global number one position from Germany and China getting ahead of India for the first time, taking the lead in Asia. The USA and China accounted for 50.8 % of the wind turbine sales in 2008 and the eight leading markets represented almost 80 % of the market for new wind turbines. One year ago, still only five markets represented 80 % of the global sales. The pioneer country Denmark fell

back to rank 9 in terms of total capacity, whilst until four years ago it held the number 4 position during several years (Fig. 5). However, with a wind power share of around 20 % of the electricity supply, Denmark is still a leading wind energy country worldwide [30].For the year 2008, USA was in top position following by Germany, Spain, China, India, Italy, France, UK, Denmark and Portugal. But Germany was in top position in 2007.

Fig. 4. Share of countries new installed capacity for 2008 [30]

Fig. 5. Top ten wind turbine installed countries (MW) [30].

5. World installation of wind turbines for 2006

The global wind energy market experienced yet another record year in 2006, demonstrating a growth of 32% over 2005 figures. According to the statistics (Table 2) issued by the Global Wind Energy Council (GWEC), 2006 saw the installation of 15197 megawatts (MW) of new capacity, taking total installed wind energy capacity to 74,223 MW. In terms of economic value, the wind energy sector is now established as an important player in the energy market, the GWEC says. The total value of new generating equipment installed in 2006 was worth €18 billion (US\$23 billion). The countries with the highest total installed capacity are Germany (20,621 MW), Spain (11,615 MW), the USA (11,603 MW), India (6,270 MW) and Denmark (3,136 MW). Thirteen countries around the world have now passed 1000 MW level for installed capacity. In terms of new capacity added in 2006, the USA led the way with 2,454 MW, followed by Germany (2,233 MW), India (1,840 MW), Spain (1,587 MW), China (1,347 MW) and France (810 MW). These figures show that new players such as China and France are gaining ground [41]. By the end of 2006, cumulative installed wind capacity of China had reached 2.6GW; the average annual growth rate over the past ten years has been 46%. Between 2004 and 2006, China's ranking in the world wind energy league moved up from the top 10 to the top 6, and the country is planning to host some of the biggest wind farms in the world. At the present growth rate, the 2010 target will be reached two years earlier. Wind power has not just contributed to supplying electricity but has lowered supply costs, reduced carbon emissions and helped to limit air pollution [42].

New capacity	MW	Market share (%)
USA	2454	16.1
Germany	2233	14.7
India	1840	12.1
Spain	1587	10.4
China	1347	8.9
France	810	5.3
Canada	776	5.1
Portugal	694	4.6
UK	634	4.2
Italy	417	2.7
Top 10 total	12 792	84.2
Rest of world	2405	15.8
World total	15 197	

Table 2. Installed capacity of top countries for January-December 2006 [41].

5.1 Europe

Europe was the leading player in the market, with 48,545 MW of installed capacity at the end of 2006 – 65% of the global total. In 2006, European wind capacity grew by 19%, producing approximately 100 TWh of electricity, equal to 3.3% of total European Union (EU) electricity consumption in an average wind year. “While Germany and Spain still represented 50% of the EU market, there was healthy trend towards less reliance on these two countries,” says Christian Kjaer, the European Wind Energy Association’s (EWEA) CEO. "In the EU, 3,755 MW was installed outside of Germany, Spain and Denmark in 2006.

In 2002, this figure still stood at only 680 MW [41]. The figures show that most of the European countries were serious about investing into wind market.

Following the agreement reached in March 2008 by the Heads of State [43], the European Union has committed itself to achieving, by 2020, that 20% of the energy it consumes comes from renewable energies and that its CO₂ emissions are cut by 20% in comparison with 1990 levels (30% if other developed countries join the effort) [44]. Wind is the most dynamic renewable energy in Europe and in the world; it already covers 3% of electricity demand in the EU – up to 23% in Denmark and around 8% in Spain and Germany [45] and is the second largest attractor of energy investments after natural gas [44,46]. Germany with total amount of 20,622 MW, Spain with 11,615 MW and Denmark with 3,136 MW installed wind power capacity were in top positions in Europe. It shows that there was a tremendous need for renewable energies like wind in order to combat high price of fossil fuel. Europe with 48,545 MW of installed wind power capacity in 2006 was in top position which is admirable.

5.2 Asia

Asia experienced the strongest increase in installed capacity outside of Europe, with an addition of 3,679 MW. This took the continent's total to over 10,600 MW. In 2006, wind capacity in Asia grew by 53% and accounted for 24% of new installations. The strongest market remains India, which installed over 1,840 MW of new capacity in 2006, increasing its total to 6,270 MW. China more than doubled its total installed capacity in 2006, taking it up to 2,604 MW by installing 1,347 MW of capacity, making it the sixth largest market worldwide. The Chinese market was boosted by the country's new Renewable Energy Law, which entered into force on 1 January 2006 [41].

In 2006, the burning of coal produced two-thirds of the primary energy consumed in China. Even with improvements in end-use energy efficiency, energy demand continues to grow and so does the air pollution. In China, pollution is causing serious health problems; crop damage and acid rain, all of which are taking a social and economic toll [42]. Air pollution has been a very serious problem in China, therefore government has implemented new regulations toward using renewable energies in order to decrease CO₂. They plan to have 5,000 MW of wind energy by the year 2010. India with total amount of 6,270 MW, China with 2604 MW and Japan with 1394 MW installed wind power capacity were in top positions in Asia. It shows that there was a great effort and attention in these countries toward using wind energy. The reason might be high cost of fossil fuel which was imported from Persian Gulf countries.

5.3 North America

North America accounted for 22% of the world's new installed wind capacity in 2006. For the second year running, the US wind energy industry installed nearly 2,500 MW, making it the country with the most new wind power. "Wind's exponential growth reflects the nation's increasing demand for clean, safe and domestic energy, and continues to attract both private and public sources of capital," comments Randy Swisher, president of the American Wind Energy Association (AWEA). "New generating capacity worth US \$4 billion was installed in 2006, billing wind as one of the largest sources of new power generation in the country – second only to natural gas – for the second year in a row." Canada also had a record year, with the installed capacity more than doubling from 683 MW in 2005 to 1459 MW at the end of 2006. "Wind energy is an emerging Canadian success story and 2006 will

be remembered as the year that our country first began to seriously capture its economic and environmental benefits,” according to Robert Hornung, president of the Canadian Wind Energy Association (CanWEA). “Canada’s on the cusp of a wind energy boom as provincial governments are now targeting to have a minimum of 10,000 MW of installed wind energy capacity in place by 2015” [41]. USA with total amount of 11,603 MW and Canada with 1,459 MW installed wind power capacity were only countries in North America.

5.4 Latin America and Caribbean

Brazil with total amount of 237 MW, Mexico with 88 MW and Costa Rica with 74 MW installed wind power capacity were in top positions in Latin America & Caribbean. It shows that there was not tendency for wind turbine installation in this part of the world. Reason could be high resources of fossil fuel in countries like Mexico and also great attention toward manufacturing of methanol in Brazil.

5.5 Rest of the world

According to table 3, growth in the relatively young African and Middle Eastern market picked up considerably in 2006, with 172 MW of new installed capacity, bringing the total up to 441 MW. This represents a 63% growth. The main countries experiencing increases are Egypt, Morocco and Iran. Compared to previous years, the Australian market only experienced slow growth in 2006 [41].Egypt with total amount of 230 MW , Morocco with 124 MW and Iran with 48 MW installed wind power capacity were in top positions in Africa and Middle East. It shows that there was not too much attention in other countries in theses regions toward using wind energy. Australia with total amount of 817 MW, New Zealand with 171 MW and Pacific Island with 12 MW installed wind power capacity were in top positions in Pacific Region. Australia has been active in field of wind energy.

Table 3. Global installed wind power capacity (MW)- regional distribution[41].

6. World installation of wind turbines for 2008

In terms of continental distribution, a continuous diversification process can be watched as well: In general, the focus of the wind sector moves away from Europe to Asia and North America. Europe (Fig 6) decreased its share in total installed capacity from 65.5 % in 2006 to 61 % in the year 2007 further down to 54.6 % in 2008. Only four years ago Europe dominated the world market with 70.7 % of the new capacity. In 2008 the continent lost this position

and, for the first time, Europe (32.8 %), North America (32.6 %) and Asia (31.5 %) account for almost similar shares in new capacity. However, Europe is still the strongest continent while North America and Asia are increasing rapidly their shares. The countries in Latin America and Africa counted for respectively only 0.6 % and 0.5 % of the total capacity and fell back in terms of new installations down to respectively only 0.4 % and 0.3 % of the additional capacity installed worldwide in the year 2008[30]. Wind energy generating capacity in the US increased from about 2,500 MW in 1999 to about 21,000MW in mid 2008 and about 28,000MW in early 2009. At the same time, the costs of installed utility- scale wind projects (in constant \$/kW) declined until the early 2000s and then generally increased [21, 47, 48]. Mass production is likely to play a significant role for future cost reductions. In the last 5 years, wind farms of several hundred MW capacities have been realized in Spain and the USA [36]. Since the majority of renewable energy technologies are not profitable at current energy prices, its furtherance is not only associated with production and employment effects but with increasing cost as well. It is apparent that the cost disadvantage of renewable compared to conventional energies is crucially dependent on future prices of energies used in power plants as well as on the amount of CO₂ emission permits [19, 20]. Australian share in this regards is more than share of both Latin America and Africa.

Fig. 6. Continental share of total installed capacity 2008[30].

6.1 Europe

Europe lost its dominating role as new market but kept its leading position in terms of total installation with 66'160 MW. Germany and Spain maintained as leading markets, both showing stable growth. The most dynamic European markets were Ireland (adding 440 MW, 55 % growth) and Poland (196 MW added, 71 % growth), the first Eastern European country with a substantial wind deployment. All in all, the European wind sector showed almost stagnation with a very small increase in added capacity from 8,607 MW to 8,928 MW. The biggest market Germany is expected, after the amendment of the renewable energy law EEG, to show bigger market growth in 2009. An encouraging change happened in the UK where the

government announced the introduction of a feed-in tariff for community based renewable energy projects. However, the cap of 5 MW represents a major hurdle so that the UK wind market will still grow at moderate rates. However, without additional incentives for wind power in more EU member states, such as improved feed-in legislation, the European Union may not be able to achieve its 2020 targets for renewable energy [30]. It goes without saying that most of the European countries were in top positions in 2008. Germany and Spain were in second and third position with total capacity installed of 23,902.8 and 16,740.3 MW respectively. But Germany with 22,247.4 MW and Spain with 15,147.4 MW of total capacity installed for 2007 were in first and third positions. Italy, France, United Kingdom, Denmark and Portugal were in position of six to ten respectively for 2008. It shows great effort of European countries toward using wind energy for electricity production. Recently, because of the global economic crisis, some wind turbine manufacturing companies in Europe dismissed the workers and decreased production lines in order to combat the crisis.

6.2 Asia

Asia with the two leading wind countries China and India and 24,439 MW of installed capacity is in a position of becoming the worldwide locomotive for the wind industry. China has again doubled its installations and Chinese domestic wind turbine manufacturers have started for the first time to export their products. It can be expected that in the foreseeable future Chinese and Indian wind turbine manufacturers will be among the international top suppliers.

The Indian market has shown robust and stable growth in the year 2008. It has already a well-established wind industry which already plays a significant and increasing role on the world markets. Further countries like South Korea (already with 45 % growth rate in 2008) start investing on a larger scale in wind energy and it can be observed that more and more companies are developing wind turbines and installing first prototypes. In parallel with the market growth in the country, it can be expected that also new manufacturers will be able to establish themselves. The World Wind Energy Conference held on Jeju Island in June 2009 is expected to push the development in the region. Pakistan installed its first wind farm in the year 2008 and the Government of the country aims at further wind farms in the near future [30]. China has chosen wind power as an important alternative source in order to rebalance the energy mix, combat global warming and ensure energy security. Supportive measures have been introduced. In order to encourage technical innovation, market expansion and commercialization, development targets have been established for 2010 and 2020, concession projects offered and policies introduced to encourage domestic production [42].

China with 12,210.0 MW and India with 9,587.0 MW of total capacity installed in 2008 were in positions of fourth and fifth in the world. Japan, South Korea and Iran with total installed capacities of 1,880.0 MW, 278 MW and 823 MW respectively were in positions of 13, 27 and 35 in the world for 2008 (Table 3). The positions of Japan and South Korea for year 2007 were same as 2008, but Iran had position of 34 in 2007. Philippine, Israel, Pakistan, Jordan, Indonesia, Mongolia, Kazakhstan, Syria and South Korea were among the Asian countries with wind turbine activities in 2008.

6.3 North America

North America showed very strong growth in the year 2008, more than doubling its capacity since 2006 to 27,539 MW. Breaking two world records, the USA became the new number one worldwide in terms of added as well as in terms of total capacity. More and

more US states are establishing favorable legal frameworks for wind energy and try to attract investors in manufacturing facilities. It can be expected that the new President Obama administration will improve substantially the political frameworks for wind power in the country, especially for those types of investors that have practically been excluded from the production tax credit scheme, like farmers, smaller companies or community based projects. The credit crunch, however, may lead to delays in project development in the short term. The Canadian government has rather been hesitating. However, among the Canadian provinces Quebec and Ontario are showing increasing commitment towards an accelerated deployment of wind energy. In Quebec, contracts for new projects were signed for a total of 2000 MW, the first to be operational by 2011[30]. USA with total installed capacity of 25,170 MW and Canada with 2369 MW in 2008 were in positions of 1st and 11th in the world. But for the year 2007, USA was in position of 2nd and Canada in position of 11th.

6.4 Latin America

Many Latin American markets still showed stagnation in the year 2008 and the overall installed capacity (667 MW) in the region accounts for only 0.5 % of the global capacity. Only Brazil and Uruguay installed major wind farms in the year 2008. This slow wind deployment is especially dangerous for the economic and social prospects of the region as in many countries people are already suffering from power shortages and sometimes do not have access to modern energy services at all. However, in some countries like Argentina, Brazil, Chile, Costa Rica or Mexico many projects are under construction thus putting lights in the forecast for 2009[30]. Brazil with 338.5 MW and Mexico with 85.0 MW of total capacity installed in 2008 were in positions of 24th and 34th in the world. Costa Rica, Argentina, Uruguay and Chile with total installed capacities of 74.0 MW, 29.8 MW, 20.5 MW and 20.1 MW respectively were in positions of 37, 41, 46 and 47 in the world for 2008 (Table 4).

6.5 Africa

In spite of the huge potentials all over the continent, with world's best sites in the North and South of the continent, wind energy plays still a marginal role on the continent with 563 MW of total capacity. Several major wind farms can be found in some of the North African countries like Morocco, Egypt or Tunisia. In the year 2009 and 2010, substantial increases can be expected from projects which are already in the development stage. However, so far, the emergence of domestic wind industry in African countries is only in a very early stage. However, it is interesting to see that companies from the region are showing an increasing interest and have started investing in the wind sector. In Sub-Saharan Africa, the installation of the first wind farm in South Africa operated by an Independent Power Producer can be seen as a major breakthrough. The South African government prepares the introduction of a feed-in tariff which would create a real market, enable independent operators to invest and thus play a key role in tackling the country's power crisis. In the mid-term, small, decentralized and stand-alone wind energy systems, in combination with other renewable energies, will be key technologies in rural electrification of huge parts of so far unserved areas of Africa. [30]. Egypt with 390.0 MW and Morocco with 125.2 MW of total capacity installed in 2008 were in positions of 21st and 32nd in the world (Table 4). South Africa, Tunisia, Nigeria, Eritrea and Namibia with total installed capacities of 21.8 MW, 20.0 MW, 2.2 MW, 0.8 MW and 0.5 MW respectively were in positions of 43, 48, 64, 69 and 72 in the world for 2008.

6.6 Australia and Oceania

The region showed encouraging growth rates, reaching 1,819 MW by the end of 2008, most of it thanks to Australia. Commitments made by the Australian government to increase their efforts in climate change mitigation and expansion of renewable energies create the expectation that the Australian wind energy market will show further robust growth also in the coming years. New Zealand, after a change in government, may, however, face major delay in its switch to renewable energy [30]. Australia with 1494 MW and New Zealand with 325.3 MW of total capacity installed in 2008 were in positions of 14th and 26th in the world. Australia was in position of 16th and New Zealand was in position of 20th for the year 2007.

7. Employment issues regarding wind energy

Wind energy is often said to have positive effects on employment, but few studies have systematically dealt with this matter [26]. The development of renewable energy industries

and saving energy technologies became a way to achieve environmental objectives and a means of increasing energy self-sufficiency and employment (e.g. [49 and 50 to 55]). The use of renewable energies offers the opportunity to diminish energy dependence, reduce the emission of CO₂ and create new employment. The involvement of local agents is highly important for the future development in this field, especially in regions whose industrial mix was based on traditional energy sources [49]. Wind industry in Europe is a predominantly male business with 78% employment, where men make up majority of the labor in fields of construction, production and engineering.

One fundamental advantage of wind energy is that it replaces expenditure on mostly imported fossil or nuclear energy resources by human capacities and labor. Wind energy utilization creates many more jobs than centralized, non-renewable energy sources. The wind sector (Fig. 7) worldwide has become a major job generator: Within only three years, the wind sector worldwide almost doubled the number of jobs from 235,000 in 2005 to 440,000 in the year 2008. These 440,000 employees in the wind sector worldwide, most of them highly skilled jobs, are contributing to the generation of 260 TWh of electricity [30].

Fig. 7. Wind energy jobs worldwide [30].

The wind energy sector has grown exponentially since the end of the 1990s, especially within the European Union (EU), and this has affected the employment levels of the regions involved[26]. The expansion of renewable energies requires additional investments into production facilities as well as into the transportation and distribution grid [19]. Unemployment rates around 10% shifted the focus of the analysis of the economic effects of the German Renewable Energy Sources Act (EEG) on labor market effects, and several studies have analyzed these effects [56 to 59]. These earlier studies either focused on the effects of electricity only, or modeled the end of the German feed-in tariff system and focus on the development until 2010 [60]. Wind energy represents an attractive source of employment in Europe. Since a number of activities (construction, O&M, legal and environmental studies) are best dealt with at local level, there will always be a positive correlation between the location of the wind farm and the number of jobs it creates. The

decision of where to locate large manufacturing centers, however, seems to rely on other, often microeconomic factors, and this is where regional and municipal authorities have a role to play. Another relevant point is that wind energy employment is following the opposite trend to the general energy sector, particularly coal extraction and electricity generation, and measures that encourage the transfer of workers from general energy to wind energy will be highly beneficial from both social and economic point of view [26].Manufacturers and component manufacturers (Fig. 8) with 37% and 22% respectively make up the highest share of direct jobs in wind energy .Service companies are the third largest category, followed by project developers. Operation and Maintenance (O&M) with 11% is in next category.

Fig. 8. Direct employment by type of company in EU [26].

The development of any new industry, including wind power, can create new domestic job opportunities, and wind development is often credited with creating more jobs per dollar invested and per kilowatt-hour generated than fossil fuel power generation [61]. Direct jobs are typically created in three areas: manufacturing of wind power equipment, constructing and installing the wind projects, and operating and maintaining the projects over their lifetime [25].

In addition, there are limited global locales possessing a skilled labor force in wind power, with Denmark still representing a unique hub of skilled laborers and an experienced network of key components suppliers to support turbine manufacturers. Suzlon recently decided to base its international headquarters in Denmark to take advantage of this knowledge base, even though it has stated that it is unlikely to sell its turbines to the Danish market [25, 62].Wind energy companies in the EU employed around 104,350 people in 2008. This represents a growth of 226% with respect to 2003 [26]. Germany with total No. of 38,000 persons employed directly in wind industry is leader in Europe (Table 5). Spain and Denmark are also countries with high employment rates in wind energy business too.

Country	No. of Direct Jobs
Austria	750
Belgium	2000
Bulgaria	100
Czech	100
Denmark	17000(23500)

UK	4500
Rest of world	400

Table 5. Summary of employment profiles (direct jobs) in different EU member states [26, 50 to 55]

8. Implementation of wind turbines in buildings

A new design of a Darrieus turbine in buildings is known as Crossflex [Fig. 9 & 10] which has an innovative system for the blades. This turbine can be located on corners and ridges of the buildings which creates an interesting aesthetic view.

Most iterations of the Darrieus form have placed the turbine on a mast. Its disadvantage is requirement for a rigid foundation, because it causes bending stress on the shaft. Also, it causes high localized loads on the building structure when mounted on buildings [65].

To maximize the number of potential locations that may be exploited, and to enable variable positioning to exploit augmented airflows, the design of the cowl also allows considerable flexibility in the positioning of the turbine. Fig. 11 shows a variety of positions on a 90° corner. This could be horizontal mounting on roof pitches from flat to 45°; horizontal mounting on parapet edges; or vertical mounting on building corners in plan. This enables placement where concentration of wind occurs, for example, rising flow up vertical surfaces, or toward the prevailing wind direction on building corners or ridges. A significant development of the Crossflex concept is the new design and placement of the turbine within a cowling and the general arrangement is shown in Fig. 12. Omitting the shaft is an advantage of this system [65]. There are numerous advantages of Crossflex over conventional Darrieus turbines in terms of performance and usability. This system is at its early stage, but needs more future work. It is a promising technique for future buildings.

9. Conclusion

Renewable energy sources have been facing a growing attention in global energy markets due to many benefits associated with their importance. During past few years, a great attention was paid toward using wind energy in many countries around the world. USA; Germany, India and China were among the countries which were more successful in order to install wind turbines in recent years. It should be noted that other countries like Bulgaria

and Turkey had the highest growth rate for 2008 and 2007 respectively. In general, the focus of the wind sector moves away from Europe to Asia and North America. Europe decreased its share in total installed capacity from 65.5 % in 2006 to 61 % in the year 2007 further down to 54.6 % in 2008. Only four years ago Europe dominated the world market with 70.7 % of the new capacity. In 2008 the continent lost this position and, for the first time, Europe (32.8 %), North America (32.6 %) and Asia (31.5 %) account for almost similar shares in new capacity. Europe lost its dominating role as new market but kept its leading position in terms of total installation with 66,160 MW. Asia with the two leading wind countries China and India and 24,439 MW of installed capacity is in a position of becoming the worldwide locomotive for the wind industry. In spite of the huge potentials all over the Africa, with world's best sites in the North and South of the continent, wind energy plays still a marginal role on the continent with 563 MW of total capacity. Australia showed encouraging growth rates, reaching 1,819 MW by the end of 2008. Many Latin American markets still showed stagnation in the year 2008 and the overall installed capacity (667 MW) in the region accounts for only 0.5 % of the global capacity. North America showed very strong growth in the year 2008, more than doubling its capacity since 2006 to 27,539 MW. The wind sector worldwide has become a major job generator. Within only three years, the wind sector worldwide almost doubled the number of jobs from 235,000 in 2005 to 440,000 in the year 2008. Wind energy represents an attractive source of employment in many countries in the world. There are some activities like operation and maintenance (O&M), research and development (O&M), manufacturing and construction which are able to create jobs in wind industries.

Wind Turbines

Edited by Dr. Ibrahim Al-Bahadly

ISBN 978-953-307-221-0

Hard cover, 652 pages

Publisher InTech

Published online 04, April, 2011

Published in print edition April, 2011

The area of wind energy is a rapidly evolving field and an intensive research and development has taken place in the last few years. Therefore, this book aims to provide an up-to-date comprehensive overview of the current status in the field to the research community. The research works presented in this book are divided into three main groups. The first group deals with the different types and design of the wind mills aiming for efficient, reliable and cost effective solutions. The second group deals with works tackling the use of different types of generators for wind energy. The third group is focusing on improvement in the area of control. Each chapter of the book offers detailed information on the related area of its research with the main objectives of the works carried out as well as providing a comprehensive list of references which should provide a rich platform of research to the field.
